

Types of medium

- Homogeneous medium : properties described are always the same
- Heterogeneous medium : properties vary w/ location of sampling.

CONTINUUM APPROX : in modeling media flow, it's important to considerate
if the mean free path length of the different length scales.
fluid molec. is much smaller than the physical domain of interest.

(a) MACROscopic
(inhomogeneity)

(b) MICROscopic

(c) molecular

Fluid prop. like viscosity, density, diffusion coeff. & miscibility are determined on the molecular scale by the individual prop. of the molecules.

- (b) The flow of a single newtonian fluid in the void space of a porous medium is described on the microscopic level by the Navier - Stokes system of equations with appropriate boundary conditions.

The Creeping Flow : interface approximates the Navier - Stokes equations for the case when the Reynolds number is significantly less than 1.

This is often called Stokes flow and it is appropriate for use when viscous flow is dominant.

- (a) In order to derive a mathematical model on the macroscopic level another continuum is considered.

Each point in the continuum on the macroscopic level is assigned average values over elementary volumes of quantities on the microscopic levels.

"Representative elementary volume": the averaging process used for passing from microscopic to macroscopic level is illustrated for the porosity, a simple geometric property of the porous medium.

$$1 \ll \text{diam}(\Omega_0(x_0)) \ll L$$

The porous medium is supposed to fill the domain Ω w/ volume meas (Ω)
Let $\Omega_0(x_0)$ belongs to Ω be a subdomain of Ω centered at the point x_0 on the macroscopic level.

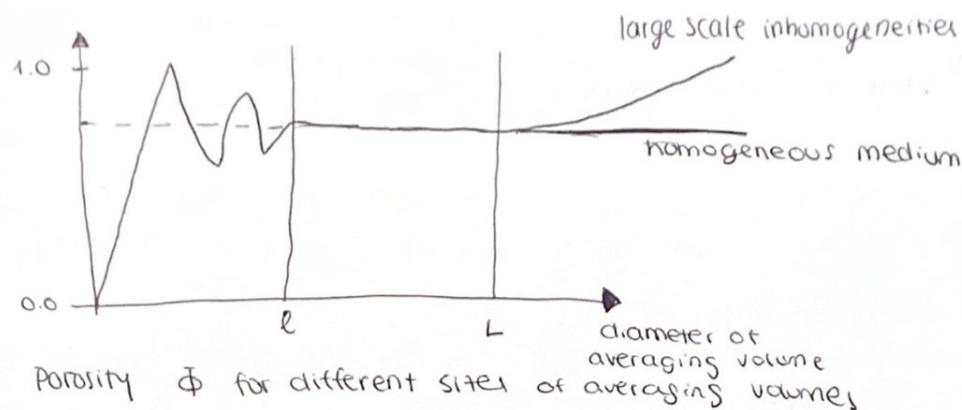

Further we define the void space indicator function on the microscopic level:

CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE

ONLINE PRIVATE LESSONS FOR SCIENCE STUDENTS
CALL OR WHATSAPP: 689 45 44 70

The macroscopic quantity porosity is obtained by averaging over the microscopic void space indicator function.

Plotting the value of $\Omega(x_0)$ at a fixed position x_0 for different diameters d of the averaging volume $\Omega_d(x_0)$.

POROUS MEDIA

- SINGLE - PHASE FLUID FLOW AND TRANSPORT
 - one fluid

Consider macroscopic eqs for flow & transport in porous media when the void space is filled w/ a single fluid

- FLUID MASS CONSERVATION

Suppose that the porous medium fills the domain $\Omega \subset \mathbb{R}^3$ then the macroscopic fluid mass conservation is expressed by the partial differential equation is given by :

$$\frac{\partial(\bar{\Phi}\rho)}{\partial t} + \nabla \cdot \{ \rho \cdot \mathbf{u} \} = \rho \cdot \mathbf{q} \quad \text{in } \Omega.$$

$\bar{\Phi}(x)$: Porosity

$\mathbf{u}(x; t)$: Macroscopic apparent velocity (m/s)

$\rho(x; t)$: Density of the fluid (kg/m^3)

$\mathbf{q}(x; t)$: Specific source/sink term with dimensions (s^{-1})

↳ either constant if incompressible or assumed to be ideal gas : $p = \rho \cdot R \cdot T$.

- DARCY'S LAW (1856)

CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70

ONLINE PRIVATE LESSONS FOR SCIENCE STUDENTS
CALL OR WHATSAPP: 689 45 44 70

\mathbf{g} : Vector pointing in the direction of gravity with size $g \text{ (m/s}^2\text{)}$

Inserting equation (18) in (17) yields a single eq for fluid pressure.

$$(19) \quad \frac{\partial(\bar{\phi} p)}{\partial t} - \nabla \cdot \left\{ \bar{\rho} \cdot \frac{K}{\mu} (\nabla p - \rho g) \right\} = \rho g \text{ in } \Omega.$$

with initial boundary conditions :

$$p(x, 0) = p_0(x) \text{ in } \Omega$$

- $p(x, t) = p_d(x, t)$ on I_d : DIRICHLET BOUNDARY

$$\frac{\partial^2 f}{\partial x_i^2} + x_i = 0; [0, 1] \text{ domain}, \quad \begin{aligned} f(0) &= \alpha_1 \text{ Numeric value} \\ f(1) &= \alpha_2 \text{ Numeric value} \end{aligned}$$

- $\bar{\rho} \cdot \mathbf{u} \cdot \mathbf{n} = \phi(x, t)$ or I_n : NEUMANN BOUNDARY

$$\frac{\partial f}{\partial x_i}(0) = \alpha_1; \quad \frac{\partial f}{\partial x_i}(1) = \alpha_2$$

In case of a compressible fluid (eq. 19) \Rightarrow Parabolic type
of an incompressible fluid \Rightarrow elliptic type \Rightarrow (initial cond. not necessary)

MICROSCOPIC CONSIDERATIONS OF MULTIPHASE SYSTEMS

Single-phase flow is governed by pressure forces arising from pressure difference within the reservoir & the exterior gravitational force.

In multiphase flows the sharp interface between fluid phases on the microscopic level give rise to a capillary force that plays an important role in this flow.

- * NOTE :
 - Darcy's law is valid for slow flow of Newtonian fluids through a porous medium with rigid solid matrix.
 - No slip boundary conditions are assumed at the fluid-solid boundary on the microscopic level.

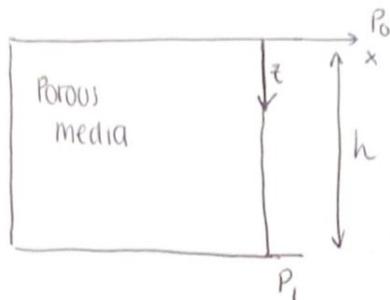

VISCOSITY FLOW BETWEEN PARALLEL PLATES

Problema de porous media

Assumptions

- 1) Incompressible
- 2) Steady state
- 3) Constant properties (μ and K constant)

Solution:

$$\cancel{\frac{\partial \phi}{\partial t}} - \nabla \cdot \left(\frac{\kappa}{\mu} (\nabla P - \rho \cdot g) \right) = \rho g$$

Since it's incompressible, ρ is out of the eq. $\rho = 0$
therefore

$$-\nabla \cdot \frac{\kappa}{\mu} (\nabla P - \rho \cdot g) = q$$

$$-\frac{d}{dz} \cdot \frac{\kappa}{\mu} \left(\frac{dP}{dz} - \rho \cdot g \right) = q$$

$$\frac{\kappa}{\mu} \left(\frac{dP}{dz} - \rho \cdot g \right) = -qz + C_1$$

$$\frac{dP}{dz} - \rho \cdot g = (-qz + C_1) \frac{\mu}{\kappa}; \quad \frac{dP}{dz} = (-qz + C_1) \frac{\mu}{\kappa} + \rho g$$

$$[P(z) = -\frac{qz^2}{2} \cdot \frac{\mu}{\kappa} + C_1 \cdot z \cdot \frac{\mu}{\kappa} + \rho g \cdot z + C_2]$$

Boundary conditions

$$z(0) = P_0; \quad z(h) = P_i$$

$$z(0) = P_0 = C_2$$

$$z(h) = P_i = -\frac{q}{2} h^2 \frac{\mu}{\kappa} + C_1 \cdot h \cdot \frac{\mu}{\kappa} + \rho g \cdot h + P_0$$

$$C_1 = \left(\frac{\kappa}{\mu} \cdot \frac{q}{2} \cdot h^2 \cdot \frac{\mu}{\kappa} \right) - \left(\frac{K \rho g h}{\mu} \right) - \left(\frac{P_0 \kappa}{\mu} - \frac{P_i \kappa}{\mu} \right)$$

$$C_1 = \frac{q h}{2} - \frac{\kappa}{\mu} \rho g + \left(P_i - P_0 \right) \frac{\kappa}{\mu h}$$

$$P(z) = -\frac{q \cdot z^2}{2} \frac{\mu}{\kappa} + \left(\frac{q h}{2} - \frac{\kappa \rho g}{\mu} + \left(P_i - P_0 \right) \frac{\kappa}{\mu h} \right) z \frac{\mu}{\kappa} + P_0$$

• CAPILLARITY

Next figure shows the interface between two phases in more detail. On the molecular level adhesive forces are attracting fluid molecules to the solid and cohesive forces are attracting molecules of one fluid to each other.

At the fluid-fluid interface these forces are not balanced leading to the curved form of the interface.

★ Viscous flow through a capillary

In cylindrical coordinates, the Stokes momentum equation becomes

$$\mu_B \cdot \frac{1}{r} \cdot \frac{\partial}{\partial r} \left(r \cdot \frac{\partial v_z}{\partial r} \right) = \frac{\Delta P}{L}$$

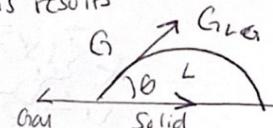

• WETTABILITY

The magnitude of the adhesive force is decreasing rapidly with distance to the wall. The interaction w , the cohesive force leads to a specific contact angle θ between the solid surface & the fluid-fluid interface that depends on the properties of the fluid.

• SURFACE TENSION

The cohesive forces are not balanced at a fluid-fluid interface. Molecules of the wetting phase fluid at the interface experience a net attraction towards the interior of the wetting phase fluid body. This results in the curved form of the interface.

$$\sigma = \frac{\Delta w}{\Delta A} \left[\frac{N}{m^2} \right] \left\{ \frac{N \cdot dx}{m^2} = \frac{N}{M} \right\}$$

CAPILLARITY PRESSURE

In order to derive a relation, it considers a tube with radius diameter $2R$ that is filled w/ a wetting phase and a non-wetting phase.

The work required to increase the area of the interface

**CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70**

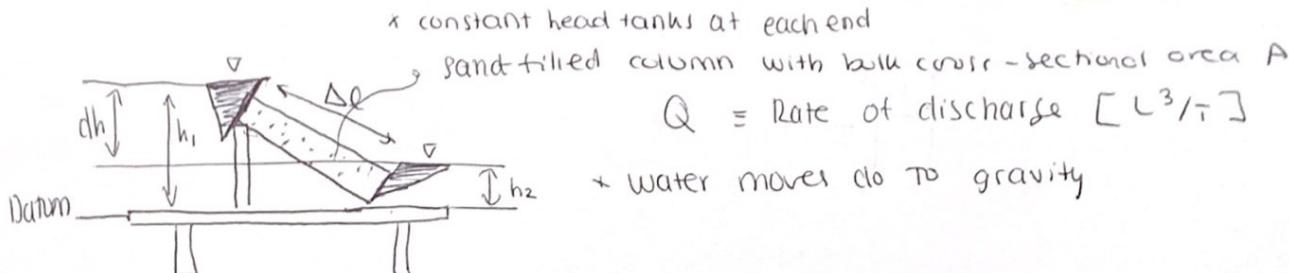

**ONLINE PRIVATE LESSONS FOR SCIENCE STUDENTS
CALL OR WHATSAPP: 689 45 44 70**

According to $P_c = \frac{2\sigma \cdot \cos\theta}{R}$, capillary pressure increases with decreasing pore size diameter.

Similar arguments relate capillary pressure (Laplace's eqs.)

$$P_c = \sigma \left(\frac{1}{r_1} + \frac{1}{r_2} \right)$$

DARCY'S LAW

For a particular sand : $Q = -K \cdot A \cdot \frac{dh}{dl}$

If we invert it we express conductivity in terms of discharge, area & gradient

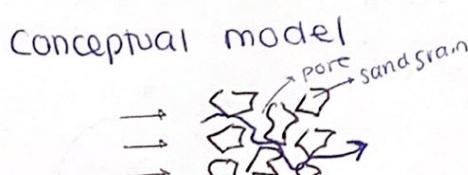

$$K = \frac{Q}{A} \left[\frac{-1}{dh/dl} \right]$$

We will look at 3 major topics important to Darcy's Law:

$$Q = K A \cdot \frac{dh}{dl}$$

Hydraulic Head Gradient
Bulk cross-sectional area of flow
Hydraulic conductivity (new name)

class explanation: $P = \rho \cdot g \cdot h$; $\frac{P}{\rho \cdot g} = h (\sim)$

There are two standard, simple models used to explain Darcy's Law, and thus to explore the Reynolds number:

→ Flow in a tube

CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE

+ Darcy's law

• FLOW in the vicinity of a sphere

- Inertial force per unit volume at any location : Rate of change of momentum
- Viscous force per unit volume.
- Dynamic similarity

Using a dimensional analysis approach,
assume that functions vary with characteristic
quantities U and R , thus

$$U \propto \frac{\partial^2 U}{\partial x^2} \propto \frac{\partial^2 U}{\partial y^2}$$

ρ = density [M/L^3]
 U = local fluid velocity [L/T]
 U = mean approach velocity [L/T]
 μ = fluid dynamic viscosity [M/LT]
 ν = fluid kinematic viscosity [L^2/T]
 x, y = cartesian coordinates [L]
 x in the direction of free stream velocity, U .

X FOR a fluid flow past a sphere : Re

$$Re = \frac{\rho \cdot U R}{\mu} = \frac{UR}{\nu}$$

X For a flow in porous media : Re

$$Re = \rho q L / \mu$$

where
 q = specific discharge
 L = characteristic pore dimension
* sand : $L = d_{50}$

When does Darcy's law apply in a porous media?

- For $Re < 1$ to 10

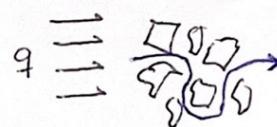

- Flow is laminar and linear
- Darcy's law applies

$$Re = \frac{\rho \cdot q d_{50}}{\mu} = \frac{q d_{50}}{\nu}$$

- For $Re \geq 1$ to 10

- Flow is still laminar but not linear
- Inertial forces becoming important
- Linear Darcy's Law no longer applies

$$Re = \frac{\rho \cdot q d_{50}}{\mu} = \frac{q d_{50}}{\nu}$$

* Notice that Darcy's Law starts to fail when inertial effects are important,
even though the flow is still laminar.

Specific Discharge, q

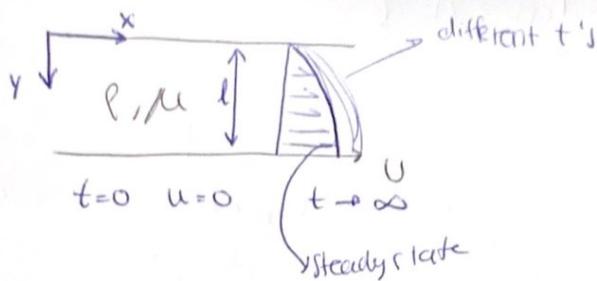

$$Q = -KA \cdot \frac{dh}{dx}$$

Since we want to know water "height," divide by A to get

HWK : Problem # 3

Assumptions

- Incompressible
- 1D flow
- Pressure gradient is negligible
- No gravity

Continuity eq. $\frac{\partial u}{\partial x} = 0 \quad u(y, +)$

Momentum eq. $\frac{\partial u}{\partial t} = V \cdot \frac{\partial^2 u}{\partial y^2}$

Superposition principle:

$$\overrightarrow{u(y, +)} = \overrightarrow{u_y(y)} + \overrightarrow{u_t(y, +)}$$

$$u(y, +) = u_y + u_t$$

Boundary conditions

$$\begin{cases} u(0, +) = 0 \\ u(-l, +) = u \\ u(y, 0) = 0 \end{cases}$$

u_y the boundary conditions (steady state)

$$\begin{aligned} u_y(0) &= 0 \\ u_y(-l) &= u \end{aligned}$$

$$u_y = -\frac{u}{l} y$$

u_t(y, +) BC's

$$u(+, 0) = u_y(0) + u_t(0, +) = 0 ; \quad u_t(0, +) = 0$$

$$u(-l, +) = u = u_y(-l) + u_t(-l, +) ; \quad u_t(-l, +) = 0$$

Initial condition:

$$u(y, 0) = u_y(0) + u_t(0, 0) = 0 ; \quad u_t(0, 0) = -u_y(0)$$

$$\left\{ \begin{array}{l} \Gamma_{(4)} - \frac{x^2}{\ell^2} + \Gamma_{(4)} = 0 \Rightarrow \Gamma_{(4)} = A \cdot e^{(\frac{x^2}{\ell^2} \cdot V \cdot t)} \end{array} \right.$$

$$Y_{(4)} - \frac{x^2}{\ell^2} \cdot Y_{(4)} = 0 \\ (Y'' + aY' + bY)$$

Resolución de una función

$$\zeta^2 = a \zeta + b = 0$$

$$\zeta_1 = \frac{-a + \sqrt{a^2 - 4b}}{2} = +\frac{x}{\ell}$$

$$\zeta_2 = \frac{-a - \sqrt{a^2 - 4b}}{2} = -\frac{x}{\ell}$$

$$\left[B \cdot e^{-\zeta_1 y} + C \cdot e^{\zeta_2 y} \right]$$

$$Y(y) = B \cdot \cos\left(\frac{x}{\ell} y\right) + C \cdot \sin\left(\frac{x}{\ell} y\right)$$

→ esto es repaso
de ecuaciones
diferenciales!!

Analizamos:

$$\Gamma_{(4)} = A \cdot e^{(\frac{x^2}{\ell^2} V t)} \quad \left\{ \begin{array}{l} x^2 < 0 \quad \checkmark \\ x^2 = 0 \quad \times \quad \rightarrow \text{no son válidos para} \\ x^2 > 0 \quad \times \quad \text{este problema.} \end{array} \right.$$

así es como descubrimos que x es negativo.

entonces

$$\zeta^2 = a \zeta + b = 0$$

$$\zeta_1 = \frac{-a + \sqrt{a^2 - 4b}}{2} = +\frac{x}{\ell} i$$

$$\zeta_2 = \frac{-a - \sqrt{a^2 - 4b}}{2} = -\frac{x}{\ell} i$$

complejo / y es negativo.

$$Y(y) = B \cdot \cos\left(\frac{x^2 y}{\ell^2}\right) + C \cdot \sin\left(\frac{x^2 y}{\ell^2}\right)$$

Volvemos a que:

$$\left[U_{(4),+1} = -\frac{U}{\ell} y + A e^{(-\frac{x^2 \cdot V \cdot t}{\ell^2})} \left[B \cdot \cos\left(\frac{x^2 y}{\ell^2}\right) + C \cdot \sin\left(\frac{x^2 y}{\ell^2}\right) \right] \right]$$

esta es la
solución steady

Bound

$y \rightarrow 0 \quad U \rightarrow 0$

CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70

ONLINE PRIVATE LESSONS FOR SCIENCE STUDENTS
CALL OR WHATSAPP: 689 45 44 70

Initial conditions:

$$U_t(y,0) = A_n \cdot \sin\left(\frac{n\pi y}{l}\right) = U_y(y) = -\frac{Uy}{l}$$

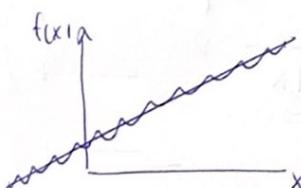

entonces, al igualarlos:

$$\boxed{A_n \cdot \sin\left(\frac{n\pi y}{l}\right) = -\frac{Uy}{l}}$$

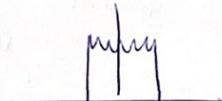

Esto es una serie de Fourier, con la forma: $f(x) = A_0 + \sum A_n \cos x + \sum B_n \sin x$
 en nuestro caso $A_0 = 0$ y $\sum A_n \cos x = 0$, así que tiene la forma:

$$f(x) = \sum B_n \cdot \sin(x)$$

Para poder aproximarla, lo hacemos a través de una sinusoidal.

ó en un pulso

Para hallar los coeficientes de la serie:

$$A_n = \frac{-2}{l} \int_0^l \frac{Uy}{l} \cdot \sin\left(\frac{n\pi y}{l}\right) dy$$

$$U(y,t) = -\frac{Uy}{l} - \frac{2U}{\pi} \sum_{n=1}^{\infty} e^{-\left(\frac{n\pi}{l}\right)^2 \cdot t} \cdot \frac{(-1)^n}{n\pi} \cdot \sin\left(\frac{n\pi y}{l}\right)$$

COMPUTATION FLUID DYNAMICS

In fluids I we had a physical domain, that had boundary conditions and was solved by differential equations.

In CFD instead of solving the diff. eq's in an analytical way, we discretize the domain to solve the diff. eq's in the nodes.

The other way of solving for fluids is through experiments.

We can use 3 different methods to solve for fluid dynamics:

Analytical / CFD / Experimental

We can also combine them.

CFD can obtain closer to reality (experiment) solution than analytically, and it's cheaper than the experimental way.

* Mesh: Is the combination of the cells used to conduct an analysis, that come from splitting the solution domain into multiple sub-domains (called cells) in the computational structure.

Two types of mesh:

Structured Mesh

or

Unstructured Mesh

A structured grid has two possible element choices: 2D - Quadrilateral & 3D - hexahedra. This model is highly space efficient since the neighbourhood relationships are defined by storage arrangement.

Is identified by irregular connectivity, it cannot be easily expressed as a 2D or 3D array in computer memory.

Combined

H Y B R I D

It integrates the

$$\frac{u}{2\Delta x} = \frac{u}{\partial x} \Big|_{ij} + (\Delta x^2) \rightarrow \text{this is a second order approximation}$$

Ejemplo CFD

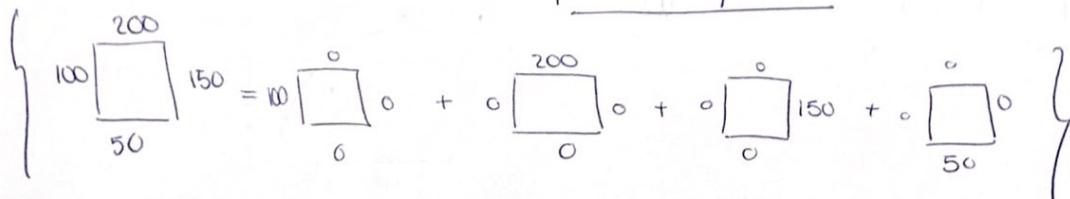

It is a plate with thermal conductivity that is constant, (K) and no source of heat.

We use the Energy equation:

$$K \left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) = 0 \quad \text{where } T = \text{temperature}$$

$$\boxed{\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} = 0} \quad \text{La Place eq} \Rightarrow \text{heat transfer.}$$

$$\circ \frac{\partial^2 T}{\partial x^2} = \frac{T_{i+1,j} + T_{i-1,j} - 2T_{ij}}{\Delta x^2}$$

$$\circ \frac{\partial^2 T}{\partial y^2} = \frac{T_{ij,j+1} + T_{ij,j-1} - 2T_{ij}}{\Delta y^2}$$

therefore:

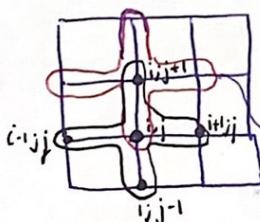

$$\frac{T_{i+1,j} + T_{i-1,j} - 2T_{ij}}{\Delta x^2} + \frac{T_{ij,j+1} + T_{ij,j-1} - 2T_{ij}}{\Delta y^2} = 0$$

and:

$$T_{ij} = \left(\frac{\Delta x^2}{\Delta y^2} \right)^{-1} \cdot \frac{1}{4} (T_{i+1,j} + T_{i-1,j} + T_{ij,j+1} + T_{ij,j-1})$$

$\Delta x = \Delta y$

Locating or i 's and j 's in the plate:

for example we can choose any node, but we could also place it in another node that will give us the info we need.

For example, fixing at node 1 where i, j :

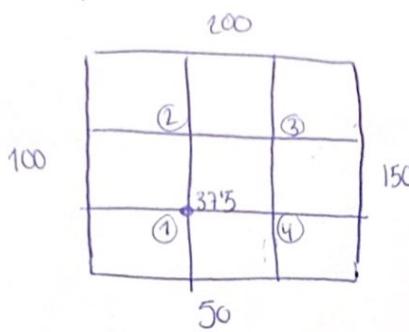

$$T_{11} = 100^\circ\text{C}$$

CALL OR WHATSAPP: 689 45 44 70**

$$T_{21} = \frac{0 + 150 + 50 + 0}{4} = 50^\circ\text{C} \quad | \text{que los q no están en el borde son } T=0.$$

Hacemos una segunda vuelta, ahora sí teniendo en cuenta las temperaturas halladas en los nodos del interior., comentando por el(1)

For node 11: $T_{11} = 37.5^\circ\text{C}$

then node 12:

$$T_{12} = \frac{T_{11} + 100 + 200 + 87.5}{4} = 106.25$$

then node 22

$$T_{22} = \frac{200 + 150 + (50) + (T_{12})}{4} = 118.75$$

then node 21

$$T_{21} = \frac{150 + 50 + 37.5 + (T_{22})}{4} = 81.75$$

+ Governing equations in CFD

- Energy eq's :

$$C_p \cdot \rho \left(\frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} \right) = k \left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) + \vec{Q}$$

$$\frac{\partial T}{\partial t} = \frac{k}{\rho C_p} \left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right)$$

$$\boxed{\alpha = \frac{k}{\rho C_p}} \rightarrow \alpha = \text{dissipation coefft}$$

example:

T_1 T_2 heat transfer is in x axis so:

$$\frac{\partial T}{\partial t} = \frac{k}{\rho C_p} \cdot \frac{\partial^2 T}{\partial x^2}, \quad \text{bc } \frac{\partial^2 T}{\partial y^2} = 0$$

$$\text{so } \left[\frac{\partial T}{\partial t} = \alpha \cdot \frac{\partial^2 T}{\partial x^2} \right] \text{ for cases like this}$$

To approximate the diff eq's in CFD (parabolic Partial Diff Eq)

- Explicit Method

- Implicit Method

Considering the example from homework :

this example could be solved analytically, but also as CFD.

1° We take assumptions:

- 1) 1D flow
- 2) Incompressible
- 3) No gravity
- 4) No gradient of pressure
- 5) Newtonian

2° X-component:

$$\left[\frac{\partial u}{\partial t} = \nu \frac{\partial^2 u}{\partial y^2} \right] \text{ this is the diff eq we need to solve}$$

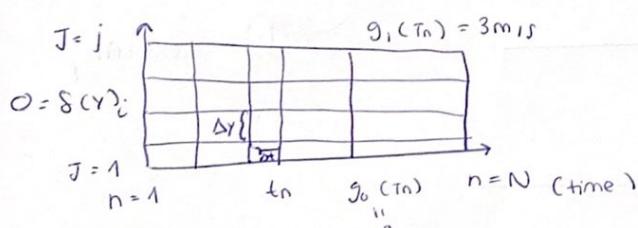

3° Boundary condition (we need the initial cond. and two B.C.'s)

- for $y = 0 \rightarrow u(0,+) = 0$
- for $y = h \rightarrow u(h,+) = 3 \text{ m/s}$

4° Initial condition ($t=0$)

$$u(y,0) = 0$$

5° we draw the domain:

Forward:

$$\frac{\partial u}{\partial t} = \frac{u_j^{n+1} - u_j^n}{\Delta t} \quad \text{Explicit mode}$$

$$\frac{\partial^2 u}{\partial y^2} = \frac{u_{j+1}^{n+1} + u_{j-1}^{n+1} - 2u_j^{n+1}}{\Delta y^2}$$

$$\frac{u_j^{n+1} - u_j^n}{\Delta t} = \nu \left(\frac{u_{j+1}^n + u_{j-1}^n - 2u_j^n}{\Delta y^2} \right)$$

$$u_j^{n+1} = \frac{\nu \Delta t}{\Delta y^2} \left(u_{j+1}^n + u_{j-1}^n - 2u_j^n \right) + u_j^n \quad \text{where } \nu = \frac{\nu \Delta t}{\Delta y^2}$$

we continue solving forward

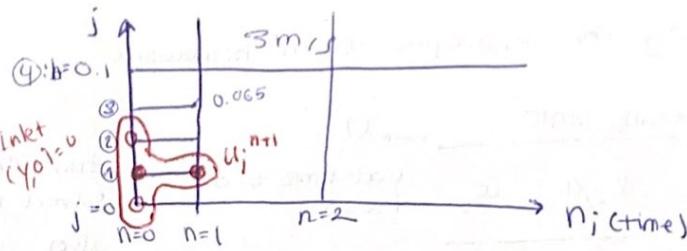

$$U_i^{n+1} = U_i^n + \lambda (U_{j+1}^n + U_{j-1}^n - 2U_i^n)$$

$h = 0.1 \text{ m}$ → separation between two plates

$$U = 3 \text{ m/s}$$

AIR:

$$\begin{cases} \rho = 1.23 \text{ kg/m}^3 \\ \mu = 1.789 \cdot 10^{-5} \frac{\text{kg}}{\text{m} \cdot \text{s}} \end{cases}$$

$j = 1 ; n = 0 (\Delta t = 1)$ where $\Delta y = 0.025$ (we've divided 0.1 m in 4)
 $\Delta t = 1 \text{ second}$ (in all cases)

$$U_i^1 = U_i^0 + (0.023) (U_2^0 + U_0^0 - 2U_1^0)$$

$\lambda = \frac{\Delta t}{(\Delta y)^2}$ viscosidad cinemática (m^2/s)

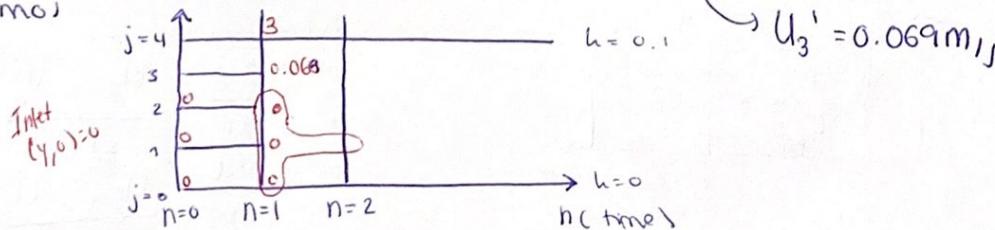

$j = 2 ; n = 0 (\Delta t = 1)$

$$U_2^1 = U_2^0 + (0.023) (U_3^0 + U_1^0 - 2U_2^0) = 0$$

$j = 3 ; n = 0 (\Delta t = 1)$

$$U_3^1 = U_3^0 + (0.023) (U_4^0 + U_2^0 - 2U_3^0) = 0.069$$

continuamos

$j = 1 ; n = 1 (\Delta t = 1 \text{ sec} \Rightarrow 2 \text{ sec})$

$$U_1^2 = U_1^1 + (0.023) (U_2^1 + U_0^1 - 2U_1^1) = 0$$

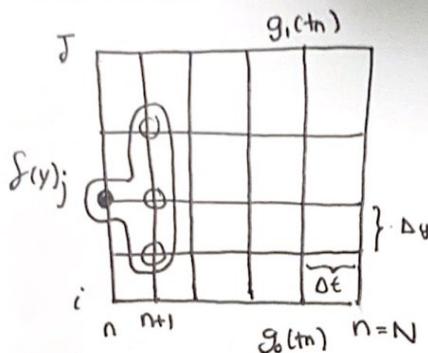

$j = 2 ; n = 2 (2 \text{ sec})$

$$U_2^2 = U_2^1 + (0.023) (U_3^1 + U_1^1 - 2U_2^1)$$

Implicit Method

$$\frac{U_j^{n+1} - U_j^n}{\Delta t} = \frac{\nu (U_{j+1}^{n+1} + U_{j-1}^{n+1} - 2U_j^{n+1})}{(\Delta y)^2}$$

$$U_j^n = -\nu (U_{j+1}^{n+1} + U_{j-1}^{n+1} - 2U_j^{n+1}) + U_j^{n+1}$$

unconditional stable

$$\frac{\Delta t}{\Delta y} \left[\lambda = \frac{\nu \Delta t}{\Delta y^2} \right]$$

$\Delta t \rightarrow \infty$ higher value

Teoría:

CFD . Generación de malla - Calidad de la malla

En las capas límite, dd las variables de flujo cambian con rapidez en la dirección normal a la pared y se requieren mallas de alta resolución en la cercanía a esta, las mallas estructuradas permiten una resolución mucho + fina que las no estructuradas.

La calidad de la malla es imprescindible para soluciones confiables de la DFC.

El tipo de sesgo + apropiado para celdas bidimensionales es el sesgo equiángulo, definido como :

$$Q_{EAS} = \text{MAX} \left(\frac{\theta_{\max} - \theta_{\text{igual}}}{180^\circ - \theta_{\text{igual}}} , \frac{\theta_{\text{igual}} - \theta_{\min}}{\theta_{\text{igual}}} \right)$$

a) Celdas triangulares

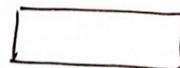

Sesgo bajo

Sesgo alto

b) Celdas cuadrilaterales

Sesgo bajo

Sesgo alto

donde :

θ_{\min} = ángulo mínimo / (en grados) entre dos lados cualesquiera de la celda
 θ_{\max} = ángulo max entre dos lados cualesquiera de la celda

θ_{igual} = ángulo entre dos lados de una celda equilátera ideal con el mismo n° de lados.
 ↪ C triangulares : $\theta_{\text{igual}} = 60^\circ$
