## 1 Introduction

In this lab we will manipulate matrices using the library numpy.

## 2 Characteristics of Matrices

### 2.1 Only Negative Values?

Write a function `all_neg(m: array) -> bool` that returns `True` if the matrix `m` contains only strictly negative values and `False` otherwise. If the matrix is empty, the function must return `True`.

#### Example

```
>>> from numpy import array
>>> all_neg(array([[ -1, -2, -3], [-4, -5, 6]]))
False
>>> all_neg(array([[ -1, -2, -3], [-3, -2, -1]]))
True
```

### 2.2 Has negative value?

Write a function `has_neg(m: array) -> bool` that returns `True` if the matrix `m` possesses at least one strictly negative value and `False` otherwise. If `m` is empty the function must return `False`.

#### Example

```
>>> from numpy import array
>>> has_neg(array([[1,2,3], [4,5,5]]))
False
>>> has_neg(array([[ -1, 3], [4,5]]))
True
```

### 2.3 Maximum Value

Write a function `max_mat(M: array) -> int` that returns the greatest value in the matrix `M`. If `m` is empty your function must return `None`.

#### Example

```
>>> from numpy import array
>>> max_mat(array([[1,9], [2,3]]))
9
>>> max_mat(array([[1,2,5], [12,-2,0]]))
12
```

### 2.4 Common Values

Write a function `common_values(A: array, B: array) -> list` that returns the list of the common values between the two matrices `A` and `B`. The matrices `A` and `B` have the same size.

### Example

```
>>> from numpy import array
>>> common_values(array([[3,-5],[4,8]]), array([[1,2], [3,8]]))
[3,8]
>>> common_values(array([[1,2,3],[-1,4,9]]), array([[3,1,4], [9,8,2]]))
[1,2,3,4,9]
```

## 2.5 Positions Of Maximum

Write a function `pos_max(M: array) -> list` that returns the positions of the maximum value in the matrix M. The returned value is a list of tuples `[(i,j), ...]` where `i` is the line number and `j` is a column number.

### Example

```
>>> from numpy import array
>>> pos_max(array([[1,3],[4,6]]))
[(1,1)]
>>> pos_max(array([[1,2,3],[3,-4,3]]))
[(0,2), (1,0), (1,2)]
```

## 3 Computations on Matrices

### 3.1 Matrix Transposition

Transposition is the operation that transforms lines into columns and vice versa. For a matrix  $M = m_{i,j}$  of size  $m \times n$ , its transpose is written as:  ${}^tM$ , has size  $n \times m$  and follows the formula:

$${}^t m_{i,j} = m_{j,i}$$

Write a function `transpose(M: array) -> array` that returns the transpose of the matrix M.

### Example

```
>>> from numpy import array
>>> transpose(array([[1,2],[3,4],[5,6]]))
array([[1,3,5],[2,4,6]])
>>> transpose(array([[1,2,3],[4,5,6]]))
array([[1,4],[2,5],[3,6]])
```

### 3.2 Matrix Multiplication

The multiplication between two compatible matrices  $A = a_{i,j}$  of size  $m \times n$  and  $B = b_{i,j}$  of size  $n \times k$  produces a matrix  $C = c_{i,j}$  of size  $m \times k$  such that  $\forall 0 < i < m$  and  $0 < j < k$ :

$$c_{i,j} = \sum_{k=0}^n a_{i,k} b_{k,j}$$

Write a function `mat_mult(A: array, B: array) -> array` that returns the multiplication between the two matrices A and B.

### Example

```
>>> from numpy import array
>>> mat_mult(array([[1,2],[4,5]]), array([[1,0], [0,1]]))
array([[1,2], [4,5]])
>>> mat_mult(array([[-1,-2], [-4,-5], [-3, -6]]), array([[1,2,3],[4,5,6]]))
array([[ -9,-12,-15], [-24,-33,-42], [-27,-36,-45]])
```

## 4 Creating Matrices

### 4.1 Count Of Successive Bases

Consider a DNA sequence, we want to count at which a base pair  $b_1$  is followed by a base pair  $b_2$ . We will create a matrix where the lines correspond to the base  $b_1$  and the columns to the base  $b_2$ . As there are 4 bases, A,T,G,C, the matrix will be of size  $4 \times 4$ , where we consider the mapping:

- A  $\rightarrow$  0
- T  $\rightarrow$  1
- G  $\rightarrow$  2
- C  $\rightarrow$  3

Write a function `count_succ(s: str) -> array` that returns the matrix presented above given the string `s`.

### Example

```
>>> count_succ("ATTGTGACT")
array([[0,1,0,1], [0,1,2,0], [1,1,0,0], [0,1,0,0]])
>>> count_succ("AAAAATGAGTA")
array([[4,1,1,0], [1,0,1,0], [1,1,0,0], [0,0,0,0]])
```
