

C.7 Derivatives

Problem 7.1

(i)

$$h'(x) = \frac{f(x)f'(x) + g(x)g'(x)}{\sqrt{f(x)^2 + g(x)^2}}.$$

(ii)

$$h'(x) = \frac{1}{1 + \left(\frac{f(x)}{g(x)}\right)^2} \cdot \frac{f'(x)g(x) - f(x)g'(x)}{g(x)^2} = \frac{f(x)g'(x) - f'(x)g(x)}{f(x)^2 + g(x)^2}.$$

(iii)

$$h'(x) = f'(g(x))g'(x)e^{f(x)} + f(g(x))f'(x)e^{f(x)} = [f'(g(x))g'(x) + f(g(x))f'(x)]e^{f(x)}.$$

(iv) First of all $h(x) = \log(g(x)) + \log(\sin f(x))$, so

$$h'(x) = \frac{g'(x)}{g(x)} + \frac{f'(x)\cos f(x)}{\sin f(x)} = \frac{g'(x)}{g(x)} + f'(x)\cot f(x).$$

(v) We first write $f(x)^{g(x)} = \exp\{g(x)\log f(x)\}$. Then

$$\begin{aligned} h'(x) &= \left[g'(x)\log f(x) + \frac{g(x)f'(x)}{f(x)} \right] \exp\{g(x)\log f(x)\} \\ &= \left[g'(x)\log f(x) + \frac{g(x)f'(x)}{f(x)} \right] f(x)^{g(x)} \\ &= f(x)^{g(x)}g'(x)\log f(x) + g(x)f'(x)f(x)^{g(x)-1}. \end{aligned}$$

(vi)

$$h'(x) = -\frac{1}{[\log(f(x) + g(x)^2)]^2} \cdot \frac{f'(x) + 2g(x)g'(x)}{f(x) + g(x)^2}.$$

Problem 7.2 In both items we are asked to figure out a function $g(x)$ such that

$$f(x) = \begin{cases} 1, & |x| \leq 1, \\ 0, & |x| \geq 2, \\ g(x), & 1 < x < 2, \\ g(-x), & -2 < x < -1, \end{cases}$$

is the requested function.

**CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE

**ONLINE PRIVATE LESSONS FOR SCIENCE STUDENTS
CALL OR WHATSAPP: 689 45 44 70**

- (b) Since the derivative of f for $|x| < 1$ and $|x| > 2$ is 0, now we need $g(x)$ to satisfy also $g'(1) = g'(2) = 0$. These are four equations, so the simplest function would be a polynomial with four unknown coefficients, namely $g(x) = ax^3 + bx^2 + cx + d$. Thus, since $g'(x) = 3ax^2 + 2bx + c$,

$$\begin{cases} g(1) = 1, \\ g(2) = 0, \\ g'(1) = 0, \\ g'(2) = 0, \end{cases} \Leftrightarrow \begin{cases} a + b + c + d = 1, \\ 8a + 4b + 2c + d = 0, \\ 3a + 2b + c = 0, \\ 12a + 4b + c = 0, \end{cases} \Leftrightarrow \begin{cases} a = 2, \\ b = -9, \\ c = 12, \\ d = -4. \end{cases}$$

Hence $g(x) = 2x^3 - 9x^2 + 12x - 4 = (x - 2)(2x^2 - 5x + 2)$.

There is a simpler way to achieve the same result. It amounts to finding a continuous and differentiable function with a local maximum and a local minimum. One such function is $\cos^2 a(x - b)$. This function reaches a maximum at $x = b$, where it is 1, and a minimum at $a(x - b) = \pi/2$, where it is 0. If we want the maximum to be at $x = 1$ then we must choose $b = 1$. If we want the minimum to be at $x = 2$ we must choose $a(2 - 1) = \pi/2$, i.e., $a = \pi/2$. Thus $g(x) = \cos^2 \frac{\pi}{2}(x - 1)$.

Problem 7.3

(i) $f'(x) = -\frac{c}{x^2}$, therefore

$$xf' + f = -\frac{c}{x} + \frac{c}{x} = 0.$$

(ii) $f'(x) = \tan x + x(1 + \tan^2 x)$, therefore

$$xf' - f - f^2 = x \tan x + x^2 - x^2 \tan^2 x - x \tan x - x^2 \tan^2 x = x^2.$$

(iii) $f'(x) = 3c_1 \cos 3x - 3c_2 \sin 3x$ and $f''(x) = -9c_1 \sin 3x - 9c_2 \cos 3x$, therefore

$$f'' + 9f = -9c_1 \sin 3x - 9c_2 \cos 3x + 9(c_1 \sin 3x + c_2 \cos 3x) = 0.$$

(iv) $f'(x) = 3c_1 e^{3x} - 3c_2 e^{-3x}$ and $f''(x) = 9c_1 e^{3x} + 9c_2 e^{-3x}$, therefore

$$f'' - 9f = 9c_1 e^{3x} + 9c_2 e^{-3x} - 9(c_1 e^{3x} + c_2 e^{-3x}) = 0.$$

(v) $f'(x) = 2c_1 e^{2x} + 5c_2 e^{5x}$ and $f''(x) = 4c_1 e^{2x} + 25c_2 e^{5x}$, therefore

$$\begin{aligned} f'' - 7f' + 10f &= 4c_1 e^{2x} + 25c_2 e^{5x} - 7(2c_1 e^{2x} + 5c_2 e^{5x}) + 10(c_1 e^{2x} + c_2 e^{5x}) \\ &= (4 - 14 + 10)e^{2x} + (25 - 35 + 10)e^{5x} = 0. \end{aligned}$$

(vi) $f'(x) = \frac{c_1 e^x - e^{-x}}{c_1 e^x + e^{-x}}$ and

**CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE

CALL OR WHATSAPP: 689 45 44 70**

- (i) Differentiating $f(x) = \arctan x + \arctan \frac{1}{x}$,

$$\frac{1}{1+x^2} + \frac{1}{1+\frac{1}{x^2}} \left(-\frac{1}{x^2} \right) = \frac{1}{1+x^2} - \frac{1}{x^2+1} = 0.$$

Therefore $f(x) = c$, a constant. To find out which constant we must evaluate $f(x)$ at any point $x > 0$, say $x = 1$. Then $f(1) = c = \arctan 1 + \arctan 1 = 2\pi/4 = \pi/2$.

- (ii) Differentiating $f(x) = \arctan \frac{1+x}{1-x} - \arctan x$,

$$\begin{aligned} f'(x) &= \frac{1}{1 + \left(\frac{1+x}{1-x}\right)^2} \frac{1-x+1+x}{(1-x)^2} - \frac{1}{1+x^2} = \frac{2}{(1-x)^2 + (1+x)^2} - \frac{1}{1+x^2} \\ &= \frac{2}{1-2x+x^2+1+2x+x^2} - \frac{1}{1+x^2} = \frac{2}{2+2x^2} - \frac{1}{1+x^2} = 0. \end{aligned}$$

Therefore $f(x) = c$, a constant. To find out which constant we must evaluate $f(x)$ at any point $x < 1$, say $x = 0$. Then $f(0) = c = \arctan 1 + \arctan 0 = \pi/4$.

- (iii) Differentiating $f(x) = 2 \arctan x + \arcsin \frac{2x}{1+x^2}$,

$$\begin{aligned}
f'(x) &= \frac{2}{1+x^2} + \frac{1}{\sqrt{1 - \left(\frac{2x}{1+x^2}\right)^2}} \frac{2(1+x^2) - 2x \cdot 2x}{(1+x^2)^2} \\
&= \frac{2}{1+x^2} + \frac{1+x^2}{\sqrt{(1+x^2)^2 - 4x^2}} \frac{2(1-x^2)}{(1+x^2)^2} = \frac{2}{1+x^2} + \frac{2(1-x^2)}{(1+x^2)\sqrt{(1-x^2)^2}} \\
&\stackrel{(*)}{=} \frac{2}{1+x^2} + \frac{2(1-x^2)}{(1+x^2)(x^2-1)} = \frac{2}{1+x^2} - \frac{2}{1+x^2} = 0,
\end{aligned}$$

where in (*) we have used the fact that $x \geq 1$ implies that $\sqrt{(1-x^2)^2} = x^2 - 1 \geq 0$. Therefore $f(x) = c$, a constant. To find out which constant we must evaluate $f(x)$ at any point $x \geq 1$, say $x = 1$. Then $f(1) = c = 2 \arctan 1 + \arcsin 1 = 2\pi/4 + \pi/2 = \pi$.

Problem 7.5 If we calculate $f'(x) = 1 + \frac{1}{3}(\sin x)^{-2/3} \cos x$ we observe that this function diverges whenever $\sin x = 0$, i.e., for $x = n\pi$ with $n \in \mathbb{Z}$. Those are the points where the tangent straight line is vertical.

Problem 7.6 Let us calculate the derivative on the left, $f'(0^-)$ and on the right, $f'(0^+)$. Since $f(0) = 0$,

$$f'(0^-) = \lim_{x \rightarrow 0^-} \frac{f(x) - f(0)}{x} = \lim_{x \rightarrow 0^-} \frac{1}{1 + e^{1/x}} = \lim_{t \rightarrow -\infty} \frac{1}{1 + e^t} = 1,$$

About differentiability,

$$f'(x) = \frac{\arccos(x+2)}{2\sqrt{x+2}} - \frac{\sqrt{x+2}}{\sqrt{1-(x+2)^2}} = \frac{\arccos(x+2)}{2\sqrt{x+2}} - \sqrt{\frac{x+2}{-3-4x-x^2}},$$

which diverges when $x = -2$ and is defined only if $x^2 + 4x + 3 = (x+1)(x+3) < 0$. This happens for $x \in (-3, -1)$, an interval that overlaps with the domain excluding the point $x = -1$. Thus the derivative exists only for $x \in (-2, -1)$.

Problem 7.8 Function $f(x)$ will be differentiable if and only if $\alpha x^2 - x + 3 \geq 0$ for all $x \in \mathbb{R}$ or $\alpha x^2 - x + 3 \leq 0$ for all $x \in \mathbb{R}$. The reason is that in either of these two cases the parabola does not cross the X axis or it just touches the axis at one point (it is only if the parabola crosses the axis that its absolute value generates points with no derivative). The condition for this to happen is that the discriminant of the parabola be ≤ 0 , i.e., $1 - 12\alpha \leq 0$. Thus $\alpha \geq 1/12$.

Problem 7.9 From the definition,

$$f'(0) = \lim_{x \rightarrow 0} \frac{f(x) - f(0)}{x} = \lim_{x \rightarrow 0} \frac{\frac{1}{x} - \frac{1}{e^x - 1} - \frac{1}{2}}{x} = \lim_{x \rightarrow 0} \frac{(2-x)(e^x - 1) - 2x}{2x^2(e^x - 1)}.$$

Now, $e^x - 1 = x + o(x)$ when $x \rightarrow 0$. This means that the denominator is $2x^2(e^x - 1) = 2x^3 + o(x^3)$ when $x \rightarrow 0$, and so we need to expand the numerator up to order $o(x^3)$. We need more terms of the exponential:

$$e^x - 1 = x + \frac{x^2}{2} + \frac{x^3}{6} + o(x^3).$$

Substituting in the numerator we have

$$(2-x)(e^x - 1) - 2x = 2x + x^2 + \frac{x^3}{3} + o(x^3) - x^2 - \frac{x^3}{2} + o(x^3) - 2x = -\frac{x^3}{6} + o(x^3).$$

Then

$$f'(0) = \lim_{x \rightarrow 0} \frac{-\frac{x^3}{6} + o(x^3)}{2x^3 + o(x^3)} = \lim_{x \rightarrow 0} \frac{-\frac{1}{6} + o(1)}{2 + o(1)} = -\frac{1}{12}.$$

Problem 7.10 Function $f(x)$ is even, so it is enough to make sure that it is continuous and differentiable at $x = c$. The function will be continuous at $x = c$ if

$$a + bc^2 = \frac{1}{c}.$$

On the other hand, for $x \geq 0$ the function is

$$\begin{cases} a + bx^2, & 0 \leq x \leq c, \\ \end{cases}$$

CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70

ONLINE PRIVATE LESSONS FOR SCIENCE STUDENTS
CALL OR WHATSAPP: 689 45 44 70

and therefore $f(x)$ will be differentiable at $x = c$ if

$$2bc = -\frac{1}{c^2} \Leftrightarrow b = -\frac{1}{2c^3}.$$

And from the previous equation we obtain

$$a = \frac{1}{c} - bc^2 = \frac{1}{c} + \frac{1}{2c} = \frac{3}{2c}.$$

So for $|x| < c$ the function is defined as

$$f(x) = \frac{1}{2c} \left(3 - \frac{x^2}{c^2} \right).$$

Problem 7.11

- (a) The two pieces defining this function are continuous and differentiable within their respective sets, so the only critical point is $x = 1$. Let us first check the continuity at this point. So

$$\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} \frac{1}{x} = 1, \quad \lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} \frac{3-x^2}{2} = 1,$$

hence

$$\lim_{x \rightarrow 1} f(x) = 1 = f(1),$$

which proves that the function is continuous also at this point. As for differentiability,

$$\begin{aligned} f'(1^+) &= \lim_{x \rightarrow 1^+} \frac{f(x) - f(1)}{x - 1} = \lim_{x \rightarrow 1^+} \frac{\frac{1}{x} - 1}{x - 1} = \lim_{x \rightarrow 1^+} \frac{1 - x}{x(x - 1)} = -1, \\ f'(1^-) &= \lim_{x \rightarrow 1^-} \frac{f(x) - f(1)}{x - 1} = \lim_{x \rightarrow 1^-} \frac{\frac{3-x^2}{2} - 1}{x - 1} = \lim_{x \rightarrow 1^-} \frac{1 - x^2}{2(x - 1)} = \lim_{x \rightarrow 1^-} \frac{(1-x)(1+x)}{2(x - 1)} \\ &= \lim_{x \rightarrow 1^-} \frac{-(1+x)}{2} = -1, \end{aligned}$$

so f is differentiable at this point and $f'(1) = -1$. Summarising, f is continuous and differentiable in \mathbb{R} .

- (b) Given that f is differentiable in \mathbb{R} , there must exist $c \in (0, 2)$ such that

$$f(2) - f(0) = f'(c)(2 - 0) \Leftrightarrow \frac{1}{2} - \frac{3}{2} = 2f'(c) \Leftrightarrow -\frac{1}{2} = f'(c).$$

We do not know whether c is in $(0, 1)$ or in $[1, 2)$, so we have to check both. We have

$$f'(x) = \begin{cases} -x, & x < 1, \\ -\frac{1}{x^2}, & x \geq 1. \end{cases}$$

**CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70**

**ONLINE PRIVATE LESSONS FOR SCIENCE STUDENTS
CALL OR WHATSAPP:689 45 44 70**

Problem 7.12 The derivative is

$$f'(x) = -\frac{2}{3x^{1/3}},$$

so f is not differentiable at $x = 0$. This is the hypothesis that is not met.

Problem 7.13

- (i) Assume that $a \leq x_1 < x_2 < \dots < x_{k-1} < x_k \leq b$ are the k points where f vanishes in $[a, b]$. In any of the $k - 1$ intervals $[x_j, x_{j+1}]$, with $j = 1, 2, \dots, k - 1$, we can apply Rolle's theorem and conclude that there must be at least a point in each of them where f' vanishes. This means that f' vanishes at least $k - 1$ times in (a, b) —hence in $[a, b]$.

- (ii) We can recursively apply the previous result and obtain

$$\begin{aligned} f \text{ vanishes } n+1 \text{ times in } [a, b] &\Rightarrow f' \text{ vanishes } n \text{ times in } [a, b] \\ f' \text{ vanishes } n \text{ times in } [a, b] &\Rightarrow f'' \text{ vanishes } n-1 \text{ times in } [a, b] \\ f'' \text{ vanishes } n-1 \text{ times in } [a, b] &\Rightarrow f''' \text{ vanishes } n-2 \text{ times in } [a, b] \\ &\vdots \\ f^{(n-1)} \text{ vanishes 2 times in } [a, b] &\Rightarrow f^{(n)} \text{ vanishes 1 time in } [a, b]. \end{aligned}$$

Problem 7.14 Let us consider the function $f(x) = x^{2/3}$ in the interval $[26, 27]$. By the mean value theorem

$$27^{2/3} - 26^{2/3} = \frac{2}{3c^{1/3}}, \quad 26 < c < 27,$$

so

$$26^{2/3} = 9 - \frac{2}{3c^{1/3}}, \quad 26 < c < 27.$$

Approximating $c \approx 27$ we obtain

$$26^{2/3} \approx 9 - \frac{2}{9} = \frac{79}{9} = 8.777777\dots$$

The exact value is $8.776382955\dots$

Taking now $g(x) = \log x$ in $[1, 3/2]$ we can write

$$\log(3/2) = \frac{1}{c} \left(\frac{3}{2} - 1 \right) = \frac{1}{2c}, \quad 1 < c < \frac{3}{2}.$$

From this we conclude

$$\frac{1}{3} < \log(3/2) < \frac{1}{2} \Leftrightarrow 0.3333333\dots < \log(3/2) < 0.5.$$

The exact value is $0.405465108\dots$

PROBLEMA 7.15

CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70

ONLINE PRIVATE LESSONS FOR SCIENCE STUDENTS
CALL OR WHATSAPP: 689 45 44 70

(ii) We can obtain the limit

$$\ell = \lim_{x \rightarrow 0} \frac{\log |\sin 7x|}{\log |x|}$$

by applying l'Hôpital's rule as

$$\ell = \lim_{x \rightarrow 0} \frac{7 \cos 7x \sin x}{\sin 7x \cos x} = \lim_{x \rightarrow 0} \frac{7 \cos 7x}{\cos x} \lim_{x \rightarrow 0} \frac{\sin x}{\sin 7x} = 7 \lim_{x \rightarrow 0} \frac{\sin x}{\sin 7x},$$

and then again,

$$\ell = 7 \lim_{x \rightarrow 0} \frac{\cos x}{7 \cos 7x} = 1.$$

(iii) Writing the limit as

$$\ell = \lim_{x \rightarrow 1^+} \frac{\log(x-1)}{\frac{1}{\log x}}$$

it becomes a ∞/∞ indeterminacy, which we can sort out using l'Hôpital's rule. Thus,

$$\ell = \lim_{x \rightarrow 1^+} \frac{\frac{1}{x-1}}{-\frac{1}{x(\log x)^2}} = \lim_{x \rightarrow 1^+} \frac{-x(\log x)^2}{x-1} = - \lim_{x \rightarrow 1^+} \frac{(\log x)^2}{x-1}.$$

And we can solve this $0/0$ indeterminacy by applying l'Hôpital's rule once more to obtain

$$-\lim_{x \rightarrow 1^+} \frac{2 \log x}{x} = 0.$$

Therefore $\ell = 0$.

(iv) This limit can be written as

$$\ell = \lim_{x \rightarrow \infty} x^{1/x} = \lim_{x \rightarrow \infty} e^{\log x / x} = \exp \left\{ \lim_{x \rightarrow \infty} \frac{\log x}{x} \right\}.$$

This new limit can be obtained by applying l'Hôpital's rule as

$$\lim_{x \rightarrow \infty} \frac{1}{x} = 0,$$

therefore $\ell = 1$.

(v) The limit

$$\ell = \lim_{x \rightarrow 0} \frac{(1+x)^{1+x} - 1 - x - x^2}{x^3}$$

is a $0/0$ indeterminacy, which can be solved by applying l'Hôpital's rule three times. The denominator becomes then 6. As for the numerator, $(1-x-x^2)''' = 0$, so we have to take three derivatives of $g(x) = (1+x)^{1+x} = e^{(1+x)\log(1+x)}$. Thus,

$$g'(x) = g(x) [\log(1+x) + 1],$$

**CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70**

**ONLINE PRIVATE LESSONS FOR SCIENCE STUDENTS
CALL OR WHATSAPP: 689 45 44 70**

(vi) We can change the variable x to $t = 1/x$. Then

$$\ell = \lim_{x \rightarrow \infty} x \left(\tan \frac{2}{x} - \tan \frac{1}{x} \right) = \lim_{t \rightarrow 0^+} \frac{\tan 2t - \tan t}{t}.$$

We can solve this 0/0 indeterminacy by applying l'Hôpital's rule to obtain

$$\ell = \lim_{t \rightarrow 0^+} \left(\frac{2}{\cos^2 2t} - \frac{1}{\cos^2 t} \right) = 1.$$

Problem 7.16 First of all, $h(0) = 0$ because if $h(0) = c \neq 0$, then

$$\lim_{x \rightarrow 0} f(x) = \lim_{x \rightarrow 0} \frac{h(x)}{x^2} = \pm\infty,$$

so f would not be continuous at $x = 0$.

Now, since the limit above is a 0/0 indeterminacy we can try to apply l'Hôpital's rule and calculate

$$\lim_{x \rightarrow 0} \frac{h'(x)}{2x}.$$

As h is twice differentiable $h'(x) \rightarrow h'(0)$ as $x \rightarrow 0$. For the same reason as above $h'(0) = 0$, otherwise it would be $\pm\infty$ and

$$\lim_{x \rightarrow 0} \frac{h(x)}{x^2} = \pm\infty,$$

again in contradiction with the fact that f is continuous at $x = 0$.

Finally, once established that $h'(0) = 0$ we can rewrite

$$\lim_{x \rightarrow 0} \frac{h'(x)}{2x} = \frac{1}{2} \lim_{x \rightarrow 0} \frac{h'(x) - h'(0)}{x} = \frac{h''(0)}{2}.$$

This limit has to be 1 if f is to be continuous at $x = 0$, thus $h''(0) = 2$.

Problem 7.17

(i) We can change the variable x to $t = 1/x$ to transform the limit

$$\ell = \lim_{x \rightarrow \infty} x \left[\left(1 + \frac{1}{x} \right)^x - e \right] = \lim_{t \rightarrow 0^+} \frac{(1+t)^{1/t} - e}{t}.$$

Since $(1+t)^{1/t} \rightarrow e$ as $t \rightarrow 0^+$ we face a 0/0 indeterminacy. Let us apply l'Hôpital's rule and calculate

$$\begin{aligned} \ell &= \lim_{t \rightarrow 0^+} (1+t)^{1/t} \left(\frac{1}{t(1+t)} - \frac{\log(1+t)}{t^2} \right) = e \lim_{t \rightarrow 0^+} \frac{t - (1+t)\log(1+t)}{t^2(1+t)} \\ &= e \lim_{t \rightarrow 0^+} \frac{t - (1+t)\log(1+t)}{t^2}, \end{aligned}$$

CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70

ONLINE PRIVATE LESSONS FOR SCIENCE STUDENTS
CALL OR WHATSAPP: 689 45 44 70

(ii) Taking logarithms in the limit we can calculate it as

$$\log \ell = \lim_{x \rightarrow \infty} \left[x^2 \log \left(1 + \frac{1}{x} \right) - x \right].$$

Now we change the variable x to $t = 1/x$ and write

$$\log \ell = \lim_{t \rightarrow 0^+} \frac{\log(1+t) - t}{t^2},$$

a 0/0 indeterminacy that can be solved by applying l'Hôpital's. Thus,

$$\log \ell = \lim_{t \rightarrow 0^+} \frac{\frac{1}{1+t} - 1}{2t} = -\frac{1}{2} \lim_{t \rightarrow 0^+} \frac{t}{t(1+t)} = -\frac{1}{2} \lim_{t \rightarrow 0^+} \frac{1}{1+t} = -\frac{1}{2}.$$

Therefore $\ell = 1/\sqrt{e}$.

(iii) This is an indeterminacy 1^∞ which can be calculated as

$$\ell = \lim_{x \rightarrow \infty} \left(\frac{2^{1/x} + 18^{1/x}}{2} \right)^x = e^c, \quad c = \lim_{x \rightarrow \infty} x \left(\frac{2^{1/x} + 18^{1/x}}{2} - 1 \right).$$

Now we change the variable x to $t = 1/x$ and write

$$\begin{aligned} c &= \frac{1}{2} \lim_{t \rightarrow 0^+} \frac{2^t + 18^t - 2}{t} = \frac{1}{2} \left(\lim_{t \rightarrow 0^+} \frac{2^t - 1}{t} + \lim_{t \rightarrow 0^+} \frac{18^t - 1}{t} \right) = \frac{1}{2} \left(\frac{d}{dt} 2^t \Big|_{t=0} + \frac{d}{dt} 18^t \Big|_{t=0} \right) \\ &= \frac{1}{2} (\log 2 + \log 18) = \log \sqrt{36} = \log 6. \end{aligned}$$

Therefore $\ell = 6$.

(iv) This limit generalises the previous one. Again,

$$\ell = \lim_{x \rightarrow \infty} \left(\frac{1}{p} \sum_{k=1}^p a_k^{1/x} \right)^x = e^c, \quad c = \lim_{x \rightarrow \infty} x \left(\frac{1}{p} \sum_{k=1}^p a_k^{1/x} - 1 \right).$$

Now we change the variable x to $t = 1/x$ and write

$$\begin{aligned} c &= \frac{1}{p} \lim_{t \rightarrow 0^+} \frac{\sum_k a_k^t - p}{t} = \frac{1}{p} \sum_{k=1}^p \lim_{t \rightarrow 0^+} \frac{a_k^t - 1}{t} = \frac{1}{p} \sum_{k=1}^p \frac{d}{dt} a_k^t \Big|_{t=0} = \frac{1}{p} \sum_{k=1}^p \log a_k \\ &= \log \left[(a_1 a_2 \cdots a_p)^{1/p} \right]. \end{aligned}$$

Therefore $\ell = (a_1 a_2 \cdots a_p)^{1/p}$.

Problem 7.18

(a) Suppose $f(0) = c \neq 0$. Then

$$\ell = \lim_{x \rightarrow \infty} \frac{f(2x^3)}{x} = +\infty$$

**CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70**

(c) Applying l'Hôpital's rule, the limit

$$\ell = \lim_{x \rightarrow 0} \frac{(f \circ f)(2x)}{f^{-1}(3x)}$$

can be obtained through the derivatives of the functions at the numerator and denominator. But

$$\frac{d}{dx}(f \circ f)(2x) = \frac{d}{dx}f(f(2x)) = f'(f(2x))f'(2x)2, \quad \frac{d}{dx}f^{-1}(3x) = \frac{3}{f'(f^{-1}(3x))},$$

and since $f(0) = 0$ also $f^{-1}(0) = 0$. Then

$$\begin{aligned} \ell &= \lim_{x \rightarrow 0} \frac{2f'(2x)f'(f(2x))f'(f^{-1}(3x))}{3} = \frac{2f'(0)f'(f(0))f'(f^{-1}(0))}{3} = \frac{2f'(0)^3}{3} \\ &= \frac{2}{3} \cdot \frac{5^3}{2^3} = \frac{125}{12}. \end{aligned}$$

Problem 7.19 Since $g(x) \rightarrow f^{-1}(1) = 0$ as $x \rightarrow 0$, this limit is a 0/0 indeterminacy. Thus we can apply l'Hôpital's rule to calculate it as

$$\ell = \lim_{x \rightarrow 0} (e^x + \cos x e^{-\sin x}) f'(f^{-1}(x+1)) = 2f'(0).$$

All that remains is to compute $f'(0)$. We can do that evaluating the equation defining $f(x)$ at $x = 0$. This yields,

$$e^{-f(0)} f'(0) = 2 \Rightarrow f'(0) = 2e,$$

since $f(0) = 1$. Thus $\ell = 4e$.

Problem 7.20

- (a) f is continuous in \mathbb{R} because so are polynomials and the absolute value function. As for differentiability, we can express f in a piecewise description as

$$f(x) = \begin{cases} 4x^3 - x^4 - 1, & 0 < x < 4, \\ x^4 - 4x^3 - 1, & \text{otherwise,} \end{cases}$$

separating out the cases where $x^3(x-4) < 0$ from those where $x^3(x-4) \geq 0$. Both pieces are differentiable (they are polynomials), so we must check the joints. Since

$$f'(x) = \begin{cases} 12x^2 - 4x^3, & 0 < x < 4, \\ 4x^3 - 12x^2, & x < 0 \text{ or } x > 4, \end{cases}$$

we have $f'(0-) = f'(0+) = 0$, so f is differentiable at $x = 0$, but $f'(4-) = -64$, and $f'(4+) = 64$, so f is not differentiable at $x = 4$.

Summarising, f is continuous in \mathbb{R} and differentiable in $\mathbb{R} - \{4\}$.

CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70

ONLINE PRIVATE LESSONS FOR SCIENCE STUDENTS
CALL OR WHATSAPP: 689 45 44 70

But this is not the whole story because f is not differentiable at $x = 4$ —hence $x = 4$ cannot be a solution to $f'(x) = 0$. We need to check this point separately. Now, $f(4) = -1$, but for any $x \neq 4$ near $x = 4$ we have $f(x) = |x^3(x-4)| - 1 > -1$, so $x = 4$ is a local minimum. Finally, -1 is the smallest value that $f(x)$ can take, and $f(0) = f(4) = -1$, so both, at $x = 0$ and at $x = 4$, function $f(x)$ reaches its absolute minimum. There is no absolute maximum though, because the function grows indefinitely as $x \rightarrow \pm\infty$.

- (c) $f(0) = -1$ and $f(1) = 2$, so Bolzano's theorem guarantees that there is at least one solution to $f(x) = 0$ in $(0, 1)$. On the other hand, in $(0, 1)$ we have $f'(x) = 4x^2(3-x) > 0$ so the function is monotonically increasing. Therefore the solution is unique.

Problem 7.21

- (a) The amount of material is proportional to the surface of the can, which is given by the formula $S = 2\pi r^2 + 2\pi rh$. But cans have all the same volume $V = \pi r^2 h$, so $h = V/\pi r^2$ and therefore

$$S = 2\pi \left(r^2 + \frac{V}{\pi r} \right).$$

Minimising the surface amounts to minimising the function

$$f(r) = r^2 + \frac{V}{\pi r}.$$

This is a differentiable function for all $r > 0$, so the minimum is reached at a solution of

$$f'(r) = 2r - \frac{V}{\pi r^2} = 0 \quad \Rightarrow \quad r^3 = \frac{V}{2\pi} \quad \Rightarrow \quad r = \left(\frac{V}{2\pi} \right)^{1/3}$$

and

$$h = \frac{V}{\pi r^2} = \left(\frac{4V}{\pi} \right)^{1/3}.$$

- (b) Lead is proportional to the surface. If the side of the square base is a and the height h , then the surface will be $S = a^2 + 4ah$. The volume constraint, $32 = a^2h$, implies $h = 32/a^2$, so

$$S = a^2 + \frac{128}{a} = f(a).$$

Now,

$$f'(a) = 2a - \frac{128}{a^2} \quad \Rightarrow \quad a^3 = 64 \quad \Rightarrow \quad a = 4, \quad h = 2.$$

- (c) We can eliminate $y = 20 - x$, so the function to maximise is

**CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE

CALL OR WHATSAPP: 689 45 44 70**

(d) If x is half the horizontal side of the rectangle, then

$$y = b\sqrt{1 - \frac{x^2}{a^2}}$$

is half the vertical side. Then the area of the rectangle is

$$A = 4xy = 4bx\sqrt{1 - \frac{x^2}{a^2}}.$$

Maximising this area is tantamount to maximising

$$f(x) = \frac{A^2}{16b^2} = x^2 - \frac{x^4}{a^2},$$

which means solving the equation

$$f'(x) = 2x - \frac{4x^3}{a^2} = 2x\left(1 - \frac{2x^2}{a^2}\right) = 0.$$

One solution is $x = 0$ —which is obviously not the right one— and the other two solutions are $x = \pm a/\sqrt{2}$. Clearly the one that maximises the area has to be $x = a/\sqrt{2}$.

(e) The picture illustrates how to construct the described triangle:

We can select an arbitrary point on the parabola, $(x_0, 6 - x_0^2)$. The slope of the tangent at that point will be $m = -2x_0$ (obtained differentiating $6 - x^2$), so the equation of the tangent straight line will be

$$y = 6 - x_0^2 - 2x_0(x - x_0) = 6 + x_0^2 - 2x_0x.$$

Now, this straight line meets the Y axis at $A(0, 6 + x_0^2)$, and the X axis at $B((6 + x_0^2)/2x_0, 0)$, so the area of the triangle will be

**CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70**

CALL OR WHATSAPP:689 45 44 70**

- (f) The area of the triangle at the base is $a^2\sqrt{3}/4$, and that of the lateral rectangles $3ah$, so the total cost will be

$$C = 0.20 \times a^2 \frac{\sqrt{3}}{4} + 0.10 \times 3ah = 0.10 \times \sqrt{3} \left(\frac{a^2}{2} + \sqrt{3}ah \right).$$

Since $128 = ha^2\sqrt{3}/4$ we get $\sqrt{3}ah = 512/a$, so $C = 0.10 \times \sqrt{3}f(a)$, where

$$f(a) = \frac{a^2}{2} + \frac{512}{a}.$$

The value of a minimising cost will be a solution of

$$f'(a) = a - \frac{512}{a^2} = 0 \Rightarrow a^3 = 512 \Rightarrow a = 8.$$

- (g) For a given $0 \leq x \leq 2$ the corresponding y on the circumference is given by

$$y = \sqrt{1 - (x - 1)^2} = \sqrt{x(2 - x)}.$$

Thus, the three points of the triangle are $A(0, 0)$, $B\left(x, \sqrt{x(2-x)}\right)$, $C(x, 0)$. The area of the triangle will then be $S = x\sqrt{x(2-x)}/2 = x^{3/2}(2-x)^{1/2}/2$. So maximising this area is tantamount to maximising

$$f(x) = 4S^2 = x^3(2-x) = 2x^3 - x^4.$$

The corresponding x will be a solution of

$$f'(x) = 6x^2 - 4x^3 = 2x^2(3 - 2x) = 0.$$

The only meaningful solution is $x = 3/2$.

- (h) Triangle similarity implies

$$\frac{y_0 + \beta}{x_0 + \alpha} = \frac{\beta}{\alpha} \Rightarrow x_0 y_0 + \beta x_0 = \beta x_0 + \beta \alpha \Rightarrow \beta = \frac{x_0 y_0}{\alpha}.$$

- (i) The length of segment AB is

$$\begin{aligned} \ell &= \sqrt{(x_0 + \alpha)^2 + (y_0 + \beta)^2} = \sqrt{(x_0 + \alpha)^2 + \left(y_0 + \frac{x_0 y_0}{\alpha}\right)^2} = \sqrt{(x_0 + \alpha)^2 + \frac{y_0^2}{\alpha^2}(x_0 + \alpha)^2} \\ &= (x_0 + \alpha) \sqrt{1 + \frac{y_0^2}{\alpha^2}}. \end{aligned}$$

So minimising ℓ is tantamount to minimising

$$f(\alpha) = \ell^2 = (x_0 + \alpha)^2 \left(1 + \frac{y_0^2}{\alpha^2}\right).$$

Differentiating

**CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE

(ii) The sum of segments OA and OB is

$$f(\alpha) = x_0 + \alpha + y_0 + \beta = x_0 + y_0 + \alpha + \frac{x_0 y_0}{\alpha}.$$

Differentiating

$$f'(\alpha) = 1 - \frac{x_0 y_0}{\alpha^2} = 0 \Rightarrow \alpha = (x_0 y_0)^{1/2}, \quad \beta = \frac{x_0 y_0}{\alpha} = (x_0 y_0)^{1/2}.$$

(iii) The area of the triangle is

$$A = \frac{1}{2}(x_0 + \alpha)(y_0 + \beta) = \frac{1}{2}(x_0 + \alpha)\left(y_0 + \frac{x_0 y_0}{\alpha}\right) = \frac{y_0}{2} \frac{(x_0 + \alpha)^2}{\alpha} = \frac{y_0}{2} \left(\frac{x_0^2}{\alpha} + 2x_0 + \alpha\right).$$

Minimising the area implies minimising

$$f(\alpha) = \frac{2A}{y_0} = \frac{x_0^2}{\alpha} + 2x_0 + \alpha.$$

Differentiating

$$f'(\alpha) = -\frac{x_0^2}{\alpha^2} + 1 = 0 \Rightarrow \alpha = x_0, \quad \beta = \frac{x_0 y_0}{\alpha} = y_0.$$

Problem 7.22

(a) For $a = 1$ the inequality becomes a trivial equality. For $a > 1$ take the function

$$f(x) = (1+x)^a - 1 - ax.$$

Differentiating,

$$f'(x) = a(1+x)^{a-1} - a = 0 \Rightarrow (1+x)^{a-1} = 1 \Rightarrow x = 0,$$

so $x = 0$ is a local extremum. From the second derivative,

$$f''(x) = a(a-1)(1+x)^{a-2} \Rightarrow f''(0) = a(a-1) > 0$$

we conclude that $x = 0$ is a minimum —the absolute minimum if $x > -1$ —, therefore $f(x) \geq f(0) = 0$ for every $x > -1$. This means

$$(1+x)^a \geq 1 + ax.$$

(b) Take the function

$$f(x) = e^x - 1 - x.$$

Differentiating,

$$f'(x) = e^x - 1 = 0 \Rightarrow x = 0,$$

**CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70**

**ONLINE PRIVATE LESSONS FOR SCIENCE STUDENTS
CALL OR WHATSAPP:689 45 44 70**

(c) Take the function

$$f(x) = \log(1+x) - \frac{x}{1+x}.$$

Differentiating,

$$f'(x) = \frac{1}{1+x} - \frac{1}{(1+x)^2} = \frac{x}{(1+x)^2} = 0 \Rightarrow x = 0,$$

so $x = 0$ is a local extremum. From the second derivative,

$$f''(x) = -\frac{1}{(1+x)^2} + \frac{2}{(1+x)^3} = \frac{1-x}{(1+x)^3} \Rightarrow f''(0) = 1 > 0,$$

we conclude that $x = 0$ is a minimum —which is absolute in this case because there is no other one when $x > -1$. Therefore $f(x) \geq f(0) = 0$ for every $x > -1$. This proves the first inequality. As for the second, take

$$g(x) = x - \log(1+x)$$

and differentiate:

$$g'(x) = 1 - \frac{1}{1+x} = \frac{x}{1+x} = 0 \Rightarrow x = 0,$$

so $x = 0$ is a local extremum. From the second derivative,

$$f''(x) = \frac{1}{(1+x)^2} \Rightarrow f''(0) = 1 > 0,$$

we conclude that $x = 0$ is a minimum —again absolute—, so $f(x) \geq f(0) = 0$ for every $x > -1$. This proves the second inequality.

Problem 7.23

(a) Take the function

$$f(x) = \frac{\log x}{x}.$$

Differentiating,

$$f'(x) = \frac{1 - \log x}{x^2} = 0 \Rightarrow x = e.$$

From the second derivative,

$$f''(x) = \frac{2\log x - 3}{x^3} \Rightarrow f''(e) = -\frac{1}{e^3} < 0,$$

**CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70**

CALL OR WHATSAPP:689 45 44 70**

Problem 7.24

- (i) The polynomial $f(x) = x^7 + 4x - 3 \sim x^7$ as $x \rightarrow \pm\infty$, so $f(x) \rightarrow \infty$ as $x \rightarrow \infty$ and $f(x) \rightarrow -\infty$ as $x \rightarrow -\infty$. Thus $f(x) = 0$ at at least one point. What we need to know is to figure out how many times $f(x)$ bends up and down and from that determining the number of times it crosses the X axis. Now,

$$f'(x) = 7x^6 + 4 > 0$$

for all $x \in \mathbb{R}$, therefore $f(x)$ increases monotonically. The conclusion is that there is only *one* solution.

- (ii) Similarly to the previous exercise, $f(x) = x^5 - 5x + 6 \sim x^5$ as $x \rightarrow \pm\infty$, so $f(x) \rightarrow \infty$ as $x \rightarrow \infty$ and $f(x) \rightarrow -\infty$ as $x \rightarrow -\infty$. Thus $f(x) = 0$ at at least one point. Now,

$$f'(x) = 5x^4 - 5 = 0 \Rightarrow x = \pm 1,$$

and from the second derivative

$$f''(x) = 20x^3 \Rightarrow f''(1) = 20 > 0, \quad f''(-1) = -20 < 0,$$

so we conclude that $x = -1$ is a local minimum and $x = 1$ a local maximum. But $f(1) = 2 > 0$ and $f(-1) = 10 > 0$, so the local minimum is above the X axis. In conclusion, there is only *one* solution.

- (iii) $f(x) = x^4 - 4x^3 - 1 \sim x^4$ as $x \rightarrow \pm\infty$, so $f(x) \rightarrow \infty$ when $x \rightarrow \pm\infty$. It is not guaranteed that there is even a single solution. From the derivative,

$$f'(x) = 4x^3 - 12x^2 = 4x^2(x - 3) = 0$$

we conclude that $x = 0$ and $x = 3$ may be extrema. $f'(x) < 0$ around $x = 0$ (at both sides), so it is an inflection point. However, close to $x = 3$ we have $f'(x) < 0$ for $x < 3$ and $f'(x) > 0$ for $x > 3$, so at $x = 3$ the polynomial reaches its absolute minimum $f(3) = -28$. Since this value is below the X axis, $f(x)$ has to cross it twice. Therefore there are *two* solutions to the equation.

- (iv) The function $f(x) = 2x - 1 - \sin x \sim 2x$ as $x \rightarrow \pm\infty$, so $f(x) \rightarrow \infty$ as $x \rightarrow \infty$ and $f(x) \rightarrow -\infty$ as $x \rightarrow -\infty$. Thus $f(x) = 0$ at at least one point. Now,

$$f'(x) = 2 - \cos x > 0 \quad \text{for all } x \in \mathbb{R},$$

so $f(x)$ monotonically increases. Therefore there is only *one* solution.

- (v) Let us first rewrite the equation. Taking logarithms the equation becomes

$$f(x) = x \log x - \log 2 = 0.$$

**CLASES PARTICULARES, TUTORÍAS TÉCNICAS ONLINE
LLAMA O ENVÍA WHATSAPP: 689 45 44 70**

**ONLINE PRIVATE LESSONS FOR SCIENCE STUDENTS
CALL OR WHATSAPP: 689 45 44 70**

(vi) Writing the equation

$$f(x) = x^2 + \log x = 0$$

we have $f(1) = 1 > 0$, and $f(x) \sim x^2$ as $x \rightarrow \pm\infty$, so $f(x) \rightarrow \infty$ as $x \rightarrow \pm\infty$. There is no guarantee that the equation has even a single solution in that interval. From the derivative,

$$f'(x) = 2x + \frac{1}{x} = \frac{2x^2 + 1}{x}$$

we conclude that $f'(x) > 0$ in $(1, \infty)$, so $f(x)$ increases monotonically. Therefore the equation has *no* solution in that interval.
